Abstract

Large language models (LLMs) possess remarkable ability to understand natural language descriptions of complex robotics environments. Earlier studies have shown that LLM agents can use a predefined set of skills for robot planning in long-horizon tasks. However, the requirement of prior knowledge of the skill set required for a given task constrains its applicability and flexibility. We present a novel approach L2S (short for Language2Subtasks) to leverage the generalization capabilities of LLMs to decompose the description of a complex task in natural language into definitions of reusable subtasks. Each subtask is defined by an LLM-generated dense reward function and a termination condition, which in turn lead to effective subtask training and chaining. However, LLMs lack detailed insight into the specific low-level control intricacies of the environment, such as threshold parameters within the generated reward and termination functions. To address this uncertainty, L2S trains parameter-conditioned subtask policies that perform well in a broad spectrum of parameter values. As the impact of these parameters for one subtask on the overall task becomes apparent only when its following subtasks are trained, L2S selects the most suitable parameter value during the training of the subsequent subtasks to effectively mitigate the risk associated with incorrect parameter choices. During training, L2S autonomously accumulates a subtask library from continuously presented tasks and their descriptions, using guidance from the LLM agent to effectively apply this subtask library in tackling novel tasks. Our experimental results show that L2S is capable of generating reusable subtasks to solve a wide range of robot manipulation tasks.

1 Introduction

In recent years, the integration of language models with robotics has opened up new avenues for advancing autonomous learning in robotic systems. Large Language models (LLMs) possess the remarkable ability to understand complex tasks and environments. Leveraging this capability, researchers have explored the use of language models in various aspects of robotics, ranging from task planning and navigation to manipulation and control. Previous work in this domain has primarily focused on leveraging language models for robot planning, where a predefined set of skills is provided to the model. However, this approach has limitations, as it assumes prior knowledge of the skill set required for the given task, thus constraining its applicability and flexibility.

Automatic skill acquisition has long been studied in the context of hierarchical reinforcement learning (Barto and Mahadevan [2003]) in the form of temporally extended actions Sutton et al. [1999].

Preprint. Under review.

Despite the proven effectiveness of skills in expediting learning (McGovern and Sutton [1998]), a fundamental question remains: how can agents autonomously develop valuable skills through interaction with their environment? There has been a significant body of work aimed at discovering skills. For example, Option-Critic (Bacon et al. [2017]) learns skills by optimizing the skill policies as well as their termination functions in a gradient-based manner, assuming all the skills can be applied everywhere. However, it is known to be prone to inefficient task decomposition, such as learning a sub-policy that terminates at every time step or discovering one efficient sub-policy that executes throughout the entire episode. Vezhnevets et al. [2017], Nachum et al. [2018], Levy et al. [2019] address this issue by automatically decomposing a complex task into subtasks and solving them by optimizing the subtask objectives. These methods excel in learning multiple levels of policies in sparse reward tasks. However, the low-level skills learned are tied to a specific environment and it is unclear whether they are adaptable to new tasks. Skill chaining (DSC) (Konidaris and Barto [2009], Bagaria and Konidaris [2020]) involves a sequential discovery and chaining of skills, starting from the end goal state and progressing backward to the initial state. However, as the agent generates new skills using the initial states of the preceding skill on the skill chain as their goal states, this poses challenges in robot manipulation tasks. For example, learning a skill π_1 to move an object towards a goal region cannot be learned well before mastering the skill π_2 for object grasping, but skill chaining would require learning π_1 first.

We present a novel approach L2S (short for "Language to Subtasks") for subtask discovery in robot learning by leveraging large language models to overcome the limitations of prior methods. We aim to empower robotic systems to autonomously discover and adapt subtasks to a wide range of tasks. L2S harnesses the generalization capability of large language models (LLMs) to decompose the natural language task description of a complex task to definitions of reusable subtasks. Each subtask is defined by an LLM-generated *dense* reward function and a termination condition, which in turn lead to effective subtask policy training and chaining for task execution. For example, consider the "turn faucet left" task depicted in Fig. 1. The GPT-4 agent can break down this task into two subtasks: (1) positioning the robot's end effector near the right side of the faucet π_{o_1} and (2) rotating the faucet handle to the left π_{o_2}. Chaining these two subtasks together successfully solves the task.

L2S excels in sequential task learning by autonomously building a library of parameterized subtasks (explained below) as it encounters tasks during training. This accumulated subtask library can then be reused to tackle new tasks, guided by the LLM agent. For example, consider a scenario where the agent is presented with the task of "turn faucet right" after it has already been trained on "turn faucet left". The LLM agent identifies that the first subtask π_{o_1} in "turn faucet left" can be tuned to position the end effector on the left side of the faucet handle (by adjusting its parameters). Thus, L2S only needs to train a new subtask π'_{o_2} to rotate the faucet handle right. By reusing existing subtask in this manner, L2S significantly reduces the computational burden associated with learning new tasks from scratch, enabling more efficient task solving over time.

The main challenge faced by L2S is that while LLMs can outline the overall structure of subtasks necessary to tackle a task, they lack detailed insight into the specific low-level control intricacies of the environment. For the "turn faucet left" task in Fig. 1, the reward function generated for the first subtask π_{o_1} encourages the subtask policy to guide the end effector towards the right side of the handle by a distance of `params[0]` = 0.01m. However, training the policy using this reward function could lead to an unforeseen outcome where the end effector ends up on the left side of the handle, rendering the subsequent subtask of rotating the faucet handle left unattainable (Fig. 1 top right). This discrepancy arises from the norm function employed in the reward and termination functions of π_{o_1}, which solely emphasizes the proximity of the end effector to the `target_position` that is located too close to the faucet handle (at a distance of `params[0]` = 0.01m). Consequently, the policy may position the end effector on the left side of the handle and still achieves a high task reward and satisfies the termination condition of this subtask. To address the uncertainty surrounding the parameters used by the LLM agent, L2S trains parameter-conditioned subtask policies, denoted as $\pi_o(a|s;\ \texttt{params})$, where the parameters `params` are akin to "goals" in goal-conditioned reinforcement learning. As the impact of these parameters on the overall task becomes apparent only when subsequent subtasks are trained, L2S adopts a strategy of training a subtask policy that performs well across a broad spectrum of parameter values and selects the most suitable parameter value during the training of subsequent subtasks. For instance, the first subtask $\pi_{o_1}(a|s;\ \texttt{params})$ for "turn faucet left" is trained to position the end effector around the faucet handle, with a distance to the handle at `params[0]`. Training the subsequent subtask π_{o_2} involves determining the correct policy parameter `params[0]` - the

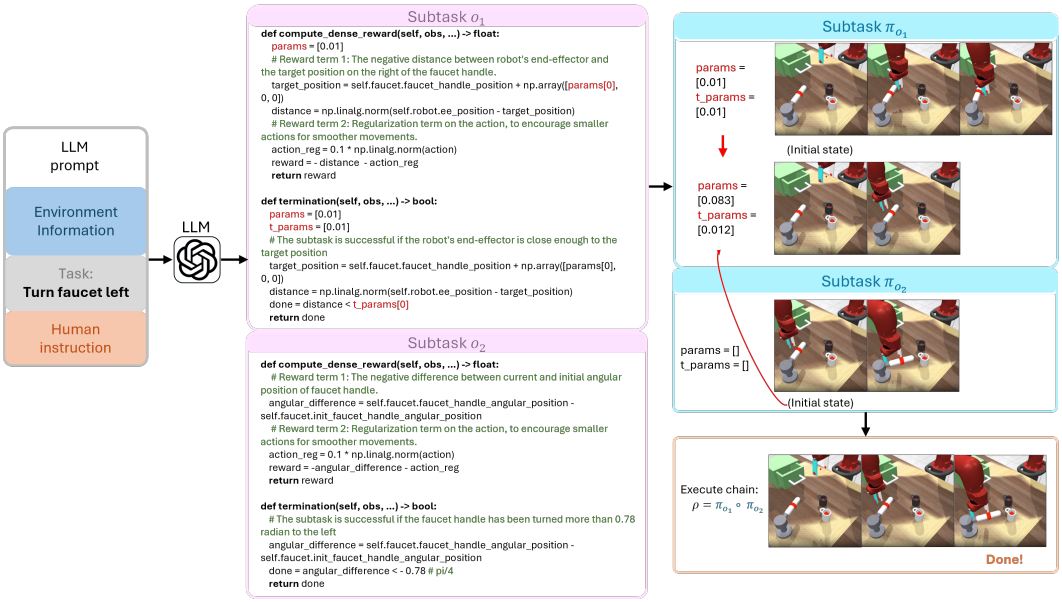

Figure 1: An example "Turn faucet left" to explain the workflow of L2S. The training of subtask π_{o_2} optimizes the policy and termination parameter of subtask π_{o_1}.

`target_position` to move the end effector to - and appropriately setting its termination condition parameters `t_params[0]` - determining how close the end effector should be to the target position before transitioning to the next subtask - to optimally achieve the highest reward during the training of the second subtask (Fig. 1 middle). In this way, L2S effectively mitigates the risk associated with potentially incorrect parameter choices. The parameter-conditioned subtask policies in L2S facilitate seamless subtask reuse. The parameter `params[0]` in the first subtask $\pi_{o_1}(a|s;\ \texttt{params})$ trained for "turn faucet left" can be adjusted to position the robot's end effector on the left side of the faucet for the "turn faucet right" task.

Compared to state-of-the-art LLM-guided reward generation methods such as Text2Reward Xie et al. [2023] and Eureka Ma et al. [2023], which generate dense reward functions to train single, monolithic policies for each robotic task, L2S instead creates reusable, parameterized subtasks for *sequential task learning*. These subtasks effectively generalize to new tasks through parameterization. While previous work, such as Ahn et al. [2022], has explored decomposing complex tasks into skills using LLMs' semantic knowledge, it relies on manually engineered skill libraries, whereas L2S autonomously learns such a library with parameterization to enable efficient generalization. Our experimental evaluations on a suite of robotics manipulation tasks show that L2S not only solves continuously presented tasks much faster but also achieves higher success rates compared to state-of-the-art methods.

2 Problem Definition

Sequential decision-making problems can be formalized as Markov Decision Processes (MDPs). An MDP is defined by a tuple $e = \langle S, A, T, R, \gamma, \eta \rangle$, where S represents the state space, A represents the action space, $T : S \times A \times S \to [0, 1]$ denotes the transition function, $R : S \times A \to \mathbb{R}$ denotes the reward function, $0 < \gamma < 1$ is the discount factor, and $s_0 \sim \eta(\cdot)$ defines the initial states. At each time step t, the agent selects an action $a_t \in A$ in state $s_t \in S$, receives a reward $r_t = R(s_t, a_t) \in \mathbb{R}$, and transitions to another state s_{t+1} with a probability determined by T. We assume **sparse reward** functions that provide signals only upon task success (1.0) or failure (0.0). The primary objective is to learn a policy $\pi : S \to A$ for e that maximizes the expected return, defined as the discounted sum of rewards: $\max_{\pi \in \Pi} \mathbb{E}_\pi \left[\sum_{t=0}^{\infty} \gamma^t R(s_t, a_t) \right]$, where $a_t = \pi(s_t)$.

Subtasks. A significant challenge for reinforcement learning (RL) algorithms lies in learning and planning over long horizons, particularly in scenarios where rewards are sparse. The options framework, proposed by Sutton et al. [1999], offers a formalism for temporal abstraction, which aids in both exploration and credit assignment. The central concept is to decompose the overarching

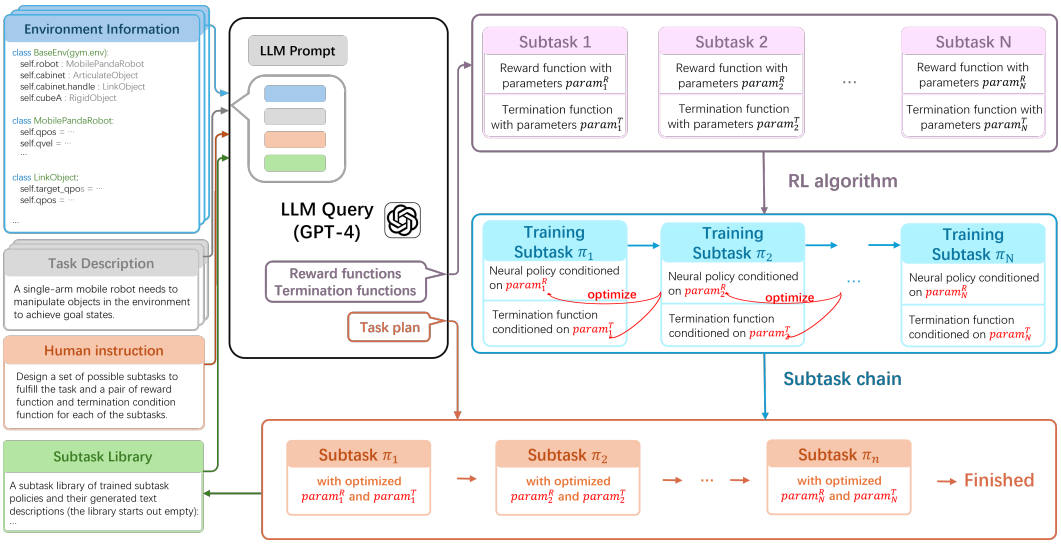

Figure 2: The L2S overall framework.

problem that the agent seeks to solve into subtasks, each typically characterized by its own reward function and capable of being accomplished by a distinct subtask. Our method L2S is inspired by the options framework and we define subtasks similar to options in the options framework. A subtask o consists of (a) its termination condition, $\beta_o(s)$, which determines whether subtask execution must terminate in state s and (b) its closed-loop subtask policy, $\pi_o(s)$, which maps state s to a low level action $a \in A$.

Subtask Chaining for Single-Task Learning. Given a *single* task MDP e, and its task description $\mathcal{L}_e$ in natural language, L2S constructs a chain of subtasks Konidaris and Barto [2009], Bagaria and Konidaris [2020] such that successful execution of each subtask in the chain allows the agent to execute another subtask. A task description $\mathcal{L}_e$ refers to a language command describing the desired goal for the agent, like "turn faucet left". The inductive bias of creating sequentially executable subtasks guarantees that as long as the agent successfully executes each subtask in its chain, it can solve the original task in e. Intuitively, subtask chaining amounts to learning subtasks such that the termination condition β_{o_i} of a subtask o_i induces an initiation condition of the subtask that follows it in the subtask chain. We formally define subtask chaining as follows. A subtask chain $\rho = o_0 \circ o_1 \circ \ldots \circ o_k$ defines a *controller* $\pi_\rho = (\pi_{o_0}, \beta_{o_0}) \circ (\pi_{o_1}, \beta_{o_1}) \circ \ldots \circ (\pi_{o_k}, \beta_{o_k})$ that navigates from an environment initial state of an MDP e to a state where β_{o_k} (the termination condition of o_k) holds. In particular, π_ρ executes π_{o_j} (starting from $j = 0$) until reaching β_{o_j}, after which it increments $j \leftarrow j + 1$ (unless $j = k$). Note that π_ρ is stateful since it internally keeps track of the index j of the current subtask policy.

Subtask Library Construction in Sequential Task Learning. The main objective of L2S is to efficiently tackle a sequence of related tasks by autonomously building a subtask library from ongoing tasks and reusing it for future tasks. Formally, given a *sequence* of tasks, where each task is represented as an MDP e and accompanied by a description $\mathcal{L}_e$, L2S builds a subtask library $\mathcal{O} \equiv \{o, L_o\}$ tailored for solving these tasks. Each subtask o within $\mathcal{O}$ is associated with a descriptive text L_o. ***The subtask library $\mathcal{O}$ starts out empty***. As L2S encounters new tasks $(e, \mathcal{L}_e)$ in the sequence, it progressively adds new subtasks in the subtask chains for solving these tasks to $\mathcal{O}$, while also developing plans that make use of the the existing subtasks in $\mathcal{O}$ whenever possible.

3 Language to Subtasks

The primary goal of L2S is to utilize LLMs to automatically build subtask libraries $\mathcal{O}$ for sequential task learning. Given the textual description of a new task, L2S uses LLMs to generate code that defines both the reward function and termination condition for each new subtask in the subtask chain for solving the task, facilitating the learning of the subtask's policy. These learned subtasks, along with their LLM-generated descriptions, are subsequently added to $\mathcal{O}$, enabling the LLMs to effectively reuse them when building subtask chains for future tasks.

3.1 Prompt Construction

For a task MDP e and its natural language task description $\mathcal{L}_e$, L2S prompts an LLM agent with an abstraction of e and $\mathcal{L}_e$ to generate a subtask chain for solving the task. The environment abstraction is needed by the LLM agent to ground reward generation for understanding how object states are represented, including robot and object configurations.We adopt a compact Pythonic representation, similar to Xie et al. [2023], as illustrated in Fig. 2. This approach offers a higher level of abstraction compared to listing all environment-specific information in a table or list format. The LLM agent is instructed to generate a skill chain for e as $\rho = o_0 \circ o_1 \circ \ldots \circ o_k$, and the reward function $\mathcal{R}_{o_i}[\phi_i](s, a)$ and termination condition $\beta_{o_i}[\varphi_i](s)$ (as python programs) for each skill o_i in ρ, where ϕ_i and φ_i are the parameters within the subtask reward and termination functions for o_i respectively. Additionally, L2S asks the LLM agent to generate a description $\mathcal{L}_o$ for each subtask o.

For continuously presented tasks, as discussed in Sec. 2, L2S maintains a subtask library $\mathcal{O} \equiv \{(o, \mathcal{L}_o)\}$ where each subtask o is accompanied with its text description $\mathcal{L}_o$ (generated by the LLM agent). L2S starts with no predefined subtasks, meaning **the subtask library $\mathcal{O}$ is initially empty**. Subtasks within the subtask chain devised for one task are added to $\mathcal{O}$ for reusing them when building subtask chains for future tasks. Thus, it is possible part of a generated subtask chain $\rho = o_0 \circ o_1 \circ \ldots$ reuses subtasks in $\mathcal{O}$. To achieve this, L2S prompts the LLM agent with the text description $\mathcal{L}_o$ of each subtask o in $\mathcal{O}$, along with a command instructing the LLM agent to select and reuse existing subtasks whenever possible.

Although LLMs have good understanding of high-level task structures, we have found that they are not yet reliable enough to generate correct rewards and termination conditions in a zero-shot manner for complex tasks. To handle this, we also prompt LLMs with few-shot examples as Xie et al. [2023]. Detailed prompt examples can be found in the Appendix G.

3.2 Subtask Chain Training

During training, L2S iteratively processes (learning and optimizing, if necessary) subtasks in a subtask chain ρ starting from the initial subtask o_0, continuing until it processes the final subtask on ρ. It maintains the property that for every subtask o_i it processes, it has already trained policies for all subtasks preceding o_i.

The key challenge with this approach is that, although LLMs can define the overarching structure of a subtask chain for a given task, they often lack precise knowledge of the low-level control details within the environment. As a result, the parameters used in the generated reward and termination functions tend to be inaccurate, reflecting inherent uncertainties (as illustrated in the turn faucet example in Sec. 1 and Fig. 1). An important aspect of L2S is that each subtask policy is parameter-conditioned (similar in concept to goal-conditioned reinforcement learning), denoted as $\pi_{o_i}(a|s;\ \phi_i)$, where ϕ_i represents the parameters in the reward function $\mathcal{R}_{o_i}$ for o_i. The training objective is for the policy $\pi_{o_i}(a|s; \phi_i)$ to maximize the expected rewards over a broad range of parameter values $\phi_i \sim \tilde{q}_{\phi_i}$, ensuring robust performance across varying conditions. The parameter distribution $\tilde{q}_{\phi_i}$ for ϕ_i is configured by the user. For example, one can set $\tilde{q}_{\phi_i}$ as a Gaussian distribution $N(v_{\phi_i}, \sigma)$, where v_{ϕ_i} is the mean centered at the LLM agent's inferred parameter values for ϕ_i, and σ is the user-defined variance. The execution of π_{o_i} is also influenced by the initial states of o_i, which are determined by both the preceding subtask policies $\pi_{o_{0:i-1}}(\phi_{0:i-1}) = \{\pi_{o_k}(a|s;\ \phi_k)$, for o_k in $\rho_{i-1}\}$ and the termination condition $\beta_{o_{0:i-1}}(\varphi_{0:i-1}) = \{\beta_{o_k}(\varphi_k)$, for o_k in $\rho_{i-1}\}$ of its preceding subtask chain ρ_{i-1} . Thus, the training for $\pi_{o_i}(a|s\ \phi_i)$ also needs to optimize the parameters associated with ρ_{i-1}, which involves finding the correct policy parameters for $\phi_{0:i-1}$ and properly setting its termination condition parameters $\varphi_{0:i-1}$:

$$\max_{\phi_{0:i-1}, \varphi_{0:i-1}, \pi_{o_i}} \mathbb{E}_{s_0 \sim \eta_{o_i}[\phi_{0:i-1}, \varphi_{0:i-1}], \phi_i \sim \tilde{q}_{\phi_i}, \tau \sim \pi_{o_i}(a_t|s_t;\phi_i)} \left[\sum_{t=0}^{T} \gamma^t \mathcal{R}_{o_i}[\phi_i](s_t, a_t) \right] \tag{1}$$

where η_{o_i} is the initial state distribution of o_i.

A key choice L2S makes is what initial state distribution η_{o_i} to choose to train the subtask policy π_{o_i}. Consider a prefix of a subtask chain $\rho_k = o_0 \circ o_1 \circ \ldots \circ o_{k-1}$, where all policies for the subtasks π_{o_0} through $\pi_{o_{k-1}}$ along the chain have been trained. L2S chooses the initial state distribution $\eta_{o_k} = \eta_{\rho_k}$ for training π_{o_k} to be the distribution of states reached by the controller π_{ρ_k} (Sec. 2) from a random environment initial state $s_0 \sim \eta$. The induced distribution η_{ρ_k} is defined inductively on the length

of ρ_k. Formally, for the zero-length path ρ_k (so $\pi_{o_k} = \pi_{o_0}$), we define $\eta_{\rho_k} = \eta$ to be the initial state distribution of the MDP e. Otherwise, we have $\rho_k = \rho_{k-1} \circ \pi_{o_{k-1}}$. Then, we define η_{ρ_k} to be the state distribution over $\beta_{o_{k-1}}$ (the termination condition of o_{k-1}) induced by any trajectory τ generated using $\pi_{o_{k-1}}$ from $s_0 \sim \eta_{\rho_{k-1}}$. Given an infinite trajectory $\tau = s_0 \to s_1 \to \ldots$ if there exists i such that $\beta_o(s_i)$ holds, we denote the smallest such i by $i(\tau, \beta_o)$. Formally, η_{ρ_k} is the probability distribution over $\beta_{o_{k-1}}$ such that for any set of states $S' \subseteq \beta_{o_{k-1}}$, the probability of S' according to η_{ρ_k} is

$$\Pr_{s \sim \eta_{\rho_k}[\phi_{k-1}, \varphi_{k-1}]}[s \in S'] = \Pr_{s_0 \sim \eta_{\rho_{k-1}}, \tau \sim \pi_{o_{k-1}}(a_t | s_t;\, \phi_{k-1})}[s_{i(\tau,\, \beta_{o_{k-1}}[\varphi_{k-1}])} \in S'].$$

We note that η_{ρ_k} is conditioned on the policy parameters $\phi_{o_{k-1}}$ of the subtask policy $\pi_{o_{k-1}}(\cdot|\cdot;\, \phi_{o_{k-1}})$ and the parameters φ_{k-1} of the termination condition $\beta_{o_{k-1}}[\varphi_{k-1}]$, while $\eta_{\rho_{k-1}}$ is unconditioned because the training of $\pi_{o_{k-1}}$ must have already optimized the parameters of subtask o_{k-2} (for $k \geq 2$).

Main Algorithm. We depict the overall subtask training algorithm of L2S in Algorithm 1. It handles a sequence of tasks $\mathcal{T} = \{(e, \mathcal{L}_e)\}$ each with task MDP e and text description $\mathcal{L}_e$. At line 3, it prompts the LLM agent with the pythonic representation of e, $\mathcal{L}_e$ and the subtask library $\mathcal{O}$ (initialized to empty) to generate the subtask chain ρ for e (Sec. 3.1). For each task, at line 5, it iteratively trains the subtasks in ρ (Sec. 3.2). When the LLM agent selects a subtask o_k from the subtask library $\mathcal{O}$, the algorithm trains the subtask controller π_{o_k}, beginning with the existing policy and value functions (and the replay buffer if using an offline RL algorithm), which often leads to policy reuse or results in fast convergence. At line 6, the algorithm incorporates the trained subtask into the subtask library $\mathcal{O}$ for reuse in future tasks. At line 9, it optimizes the parameters of the entire subtask chain ρ using the *sparse* environment reward R_e from e. The final subtask chaining controller π_ρ, constructed for ρ (line 10), is added to $\mathcal{C}$, which holds the controllers for all the tasks in the input sequence $\mathcal{T}$ (line 11).

3.3 Reinforcement Learning for Single Subtasks

We now describe how L2S learns a policy π_{o_k} for a single subtask o_k based on Equation 1 once the initial state distribution $\eta_{o_k} = \eta_{\rho_k}$ is known (Line 5 of Algorithm 1). At a high level, it trains π_{o_k} based on the reward function $\mathcal{R}_{o_k}(\phi_k)$ with the parameters $\phi_k \sim \tilde{q}_{\phi_k}$ sampled from a distribution $\tilde{q}_{\phi_k}$ (akin to "goals" in goal-conditioned reinforcement learning). Specifically, it uses Equation 2 to optimize the parameters of the preceding skill based on (freezed) π_{o_k}, which can be solved using any black-box optimization algorithms such as CEM.

$$\max_{\phi_{0:k-1}, \varphi_{0:k-1}} \mathbb{E}_{s_0 \sim \eta_{\rho_k}[\phi_{0:k-1}, \varphi_{0:k-1}], \phi_k \sim \tilde{q}_{\phi_k}, \tau \sim \pi_{o_k}(a|s;\phi_k)} \left[\sum_{t=0}^{T} \gamma^t \mathcal{R}_{o_k}[\phi_k](s_t, a_t) \right] \tag{2}$$

It uses Equation 3 to learn π_{o_k} based on the parameters of its preceding skills, which can be solved using a standard RL algorithm such as SAC [Haarnoja et al., 2018].

$$\max_{\pi_{o_k}} \mathbb{E}_{s_0 \sim \eta_{\rho_k}[\phi_{0:k-1}, \varphi_{0:k-1}], \phi_k \sim \tilde{q}_{\phi_k}, \tau \sim \pi_{o_k}(a|s;\phi_k)} \left[\sum_{t=0}^{T} \gamma^t \mathcal{R}_{o_k}[\phi_k](s_t, a_t) \right] \tag{3}$$

Our subtask training algorithm iteratively optimizes both Equation 2 and Equation 3 until convergence.

4 Experiments

Benchmarks. We demonstrate the capability of L2S across various environments and tasks within the Meta-World Yu et al. [2019] and ManiSkill2 Gu et al. [2023] benchmarks. We conducted tasks within the **LORL-Meta-World** environment Nair et al. [2021] (Fig. 3 left), a simulated domain built atop Meta-World. This environment features a Sawyer robot interacting with a tabletop setup that includes a drawer, a faucet, and two mugs. **ManiSkill2** offers a diverse range of simulated object manipulation tasks. We integrate the cube and cabinet environments into ManiSkill2 (Fig. 3). Sawyer robots in this environment can interact with two cubes and a cabinet with drawers and doors. As detailed in Table 1, we evaluated five basic tasks in each

Task3: Turn faucet right	Task3: PickCube
Task4: Push white mug backward	Task4: StackCube
Task5: Push white mug left	Task5: PlaceCubeDrawer
Task6: Turn faucet left and Open drawer	Task6: OpenDrawer, PlaceCubeDrawer and CloseDrawer

Baselines. We conducted a comparative analysis between L2S and two other state-of-the-art methods: Text2Reward (T2R) Xie et al. [2023] and Eureka Ma et al. [2023]. **T2R** utilizes LLMs to generate dense reward functions for training a single, monolithic policy per robotic task, using the same Python-based environment abstraction and task description as ours provided to the LLM. In contrast, **Eureka** employs an evolutionary approach, where it inputs the environment script into the LLM to generate multiple reward functions simultaneously for training policies in parallel. Batch success rates are then used to guide the LLM in refining reward functions for the next iteration, creating a feedback loop that iteratively improves the reward functions. For our benchmarks, we ran Eureka for 3 rounds with 8 samples per round. This process resulted in significantly higher training costs compared to L2S. We conducted multiple runs on Eureka and reported results only from those that had at least one successful sample in each round.

Ablation. We also included a variant of L2S called L2S-fixed, which uses fixed LLM-generated parameters in reward and termination functions, instead of optimizing them as in L2S , to assess the impact of addressing potentially incorrect parameter choices made by LLMs.

Experiment setup. We use GPT-4 as our LLMAgent. For reinforcement learning of subtask policies, we employ SAC Haarnoja et al. [2018], maintaining consistent hyper-parameters across all tasks and experiments within these benchmarks. To evaluate the robustness of L2S , each task was conducted using 5 different random seeds. The hyperparameters for SAC are detailed in Appendix C.

Overall Results. Fig. 4 illustrates the training results, showing the number of tasks that have converged as the total training timesteps increase. Fig. 5 displays the average evaluation success rates at convergence across all tasks. For the performance on the task sequence of 6 tasks, as shown in Fig. 4: 1) In LORL, L2S solved an average of 5.44 tasks in a total of 1.1e7 time steps, while L2S-fixed solved 4.98 tasks, and Text2Reward solved 4.9 tasks in a total of 1.5e7 time steps. 2) In

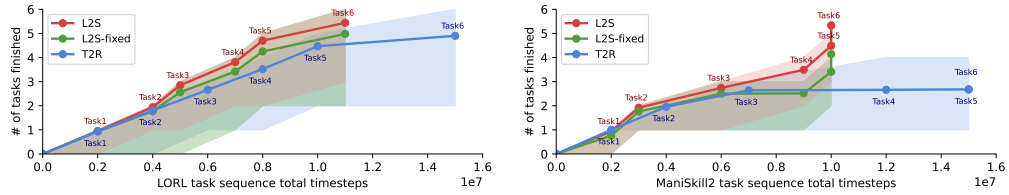

Figure 4: Given the sequence of tasks in Table 1, we report the average number of tasks trained to convergence on LORL-Meta-World (left side) and ManiSkill2 (right side), averaged over 5 random seeds. The policy is considered converged when its evaluation success rate converges to a value significantly above zero. Eureka is omitted from here because its evolutionary reward function search demands considerably more training steps than the other methods.

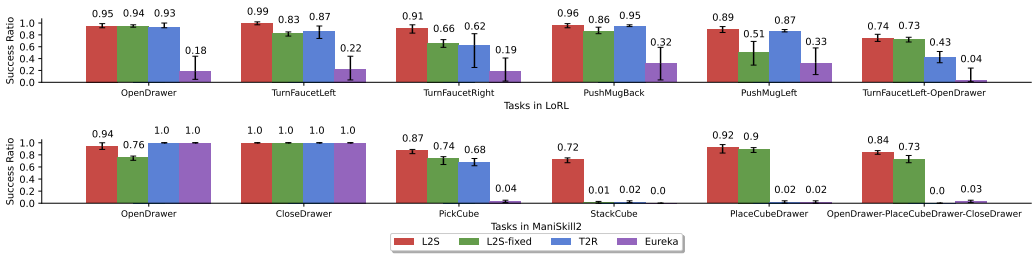

Figure 5: We report the average evaluation success rates at convergence across all tasks on LORL-Meta-World (top) and ManiSkill2 (bottom), averaged over 5 random seeds.

ManiSkill2, L2S solved an average of 5.33 tasks in a total of 1e7 time steps, while L2S-fixed solved 4.14 tasks, and Text2Reward solved only 2.68 tasks in a total of 1.5e7 time steps. Overall, L2S showed an improvement of 11.0% in LORL and 98.8% in ManiSkill2, while requiring 26.7% and 33.3% less training cost compared to the baseline Text2Reward. For the performance on single simple or complex tasks, as shown in Fig. 5, L2S outperformed the baseline Text2Reward by 18.7% and 98.7% on average success rate in LORL and ManiSkill2 environments, respectively, demonstrating a significant performance improvement with L2S.

Subtask Reusing. Although the LLM agent recognizes that this combination of tasks can be addressed by reusing existing subtasks, L2S still requires training steps to fine-tune these subtasks for adaptation to the environment due to shifts in the initial state distribution. **Specifically**, in the LORL environment, L2S leverages subtasks learned from "Turn faucet left" and "Push white mug backward" to expedite training for "Turn faucet right" and "Push white mug left" respectively. As shown in Fig. 6, the first subtask of the "Turn faucet left" task, $\pi_{o_1}(a|s;\texttt{params})$, guides the robot's end-effector to the right side of the faucet handle at a target location with `params[0]` = 0.083m away from the handle. This parameter-conditioned subtask was reused with `params[0]` = −0.095m to guide the end-effector to the opposite side of the faucet in the "Turn faucet right" task. **Similarly**, in ManiSkill2, L2S leverages the subtask for approaching the handle in the "Open Drawer" task for the "Close Drawer" task. It also reuses the subtask for grasping the cube in the "Pick Cube" task for the "Stack Cube" and "Place Cube Drawer" tasks, thereby expediting sequential task learning.

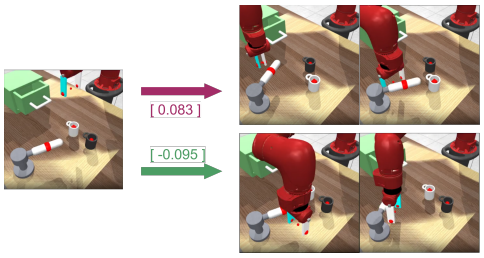

Figure 6: An example of subtask reusing. The first subtask in task "Turn faucet left" is reused for "Turn faucet right" with the optimized `params` .

Training progress evaluation. As summarized in Fig. 5, L2S significantly outperforms the baseline T2R on challenging tasks like Stack Cube. To further illustrate this performance, we present the training curves of both L2S and T2R in Fig. 7 for the PickCube and StackCube tasks. We utilized functions from the ManiSkill2 library to design evaluation functions that assess the progress of

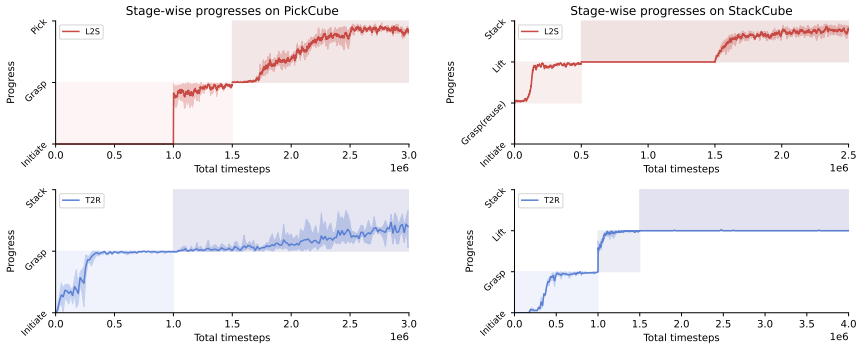

Figure 7: Left: the progress of training the task "PickCube" in ManiSkill2 measured by 2 stage-wise evaluation functions: **(1)grasp cube and (2) place cube**. Right: the progress of training the task "Stackcube" in ManiSkill2 measured by 3 stage-wise evaluation functions: **(1)grasp cube, (2) lift cube, (3) stack cube**. In sequential task learning, L2S reuses the subtasks for grasping cubes from "PickCube" in training "StackCube".

the learning agent in achieving specific key subgoals of each task. In the case of StackCube, the evaluation function gauges whether the agent has consistently mastered the abilities to grasp, lift, and stack a cube. Although T2R can generate step-wise reward functions, combining rewards across different steps proves to be difficult. In the case of PickCube or StackCube, a high grasping reward combined with a relatively lower stacking reward leads the policy to prioritize holding the cube, as ineffective stacking actions can easily result in losing contact with the cube, thus yielding a lower reward. T2R also requires significantly more training steps than L2S to achieve convergence (Fig. 4), as it learns a single monolithic policy that lacks the flexibility for easy reuse. In contrast, Fig. 7 demonstrates that L2S quickly acquires the ability to grasp a cube in StackCube by effectively reusing the grasp subtask learned during the PickCube task. Eureka faces similar challenges as T2R in generating effective step-wise reward functions, with performance declining as the complexity of the required reward functions increases.

Ablation Study. In Fig. 4, although the ablation L2S-fixed demonstrates a similar convergence rate to L2S for tasks in LORL environment, Fig. 5 reveals that it converges to sub-optimal policies. In ManiSkill environments, L2S-fixed struggles to solve more challenging tasks, such as StackCube, underscoring the necessity of optimizing LLM-generated parameters in the reward and termination functions to address the inherent uncertainty of LLM agents when dealing with low-level control intricacies. Additional ablation studies on optimizing reward functions and termination parameters under various variance settings and long-horizon tasks are provided in Appendix E.

5 Related Work and Conclusion

Recent research on the reasoning and planning capacity of large language models (LLMs) [Huang et al., 2022a,b, Lin et al., 2023] has highlighted the integration of LLMs in robotic task and motion planning (TAMP) [Firoozi et al., 2023]. Some works [Yu et al., 2023, Ma et al., 2023, Li et al., 2024] introduce new paradigms that harnesses flexibility of reward function representations by utilizing LLMs to generate reinforcement learning reward functions that can be optimized and accomplish variety of robotic tasks. L2S differs from the aforementioned works in decomposing task into subtask chain, optimizing parameters in generated functions to enhance task performance and reusing subtask chain for learning efficiency. A much broader discussion of related work in LLM Reasoning is available in Appendix A.

Conclusion. We present L2S that leverages Large Language Models (LLMs) to autonomously construct a subtask library for sequential task learning. L2S progressively builds a subtask library guided by LLMs and efficiently reuses them across new tasks, enabling the learning algorithm to effectively handle increasingly challenging environments. To handle the uncertainty in LLM-generated reward and termination functions, L2S trains a parameter-conditioned policy that perform well across a broad range of parameter values for each subtask and selects the most suitable parameter values during the training of its subsequent subtasks, mitigating the risk of incorrect parameter choices by LLMs. Experimental results demonstrate that L2S outperforms baselines in solving complex,

multi-step tasks, largely due to its ability to automatically construct a subtask library for sequential task learning. Discussion of limitations can be found in Appendix B.

A More Related Work

LLMs for Reasoning. Recent studies on large language models (LLMs), e.g. **GPT-3** [Brown et al., 2020], **GPT-4** [OpenAI et al., 2024], have demonstrated significant advancements of its reasoning capabilities. Prompting proposed by **Chain-of-Thought (CoT)** [Wei et al., 2023], has shown efficacy in improving reasoning by eliciting detailed reasoning paths in LLMs, which helps in tasks involving multi-step reasoning. Similarly, **ReAct** [Yao et al., 2023] combines reasoning with actions, enhancing performance on tasks by enabling dynamic reasoning and interactions with external information, demonstrating significant improvements. Additionally, **Zero-shot-CoT** [Kojima et al., 2023] has been proved effective in enhancing the zero-shot reasoning abilities of models across various tasks, enhancing the potential of LLMs in tasks requiring complex multi-hop thinking without the need for task-specific fine-tuning. These advancements suggests a promising direction for further enhancing the reasoning powers of LLMs through advanced prompting techniques and integrated reasoning-action paradigms. We leverage such reasoning ability to make LLMs understand the semantics of robotic tasks and follow the instructions from human correctly.

LLM Planning for Robotics. Recent research has highlighted the integration of Large Language Models (LLMs) in robotic task and motion planning (TAMP) [Firoozi et al., 2023]. Huang et al. [2022a] investigated LLMs for direct trajectory planning, revealing limitations in spatial and numerical reasoning that necessitate frequent re-prompting to align with task constraints. Following works aim to mitigate the gap on feasibility and correctness when applying LLM-generated plans to simulated or real-world robotic environments. Inspired by the in-context learning ability of LLMs, **Inner Monologue** [Huang et al., 2022b] allows robotic systems to integrate real-time environmental feedback into LLM-generated plans. This strategy significantly enhances the adaptability and effectiveness of robotic agents by using continuous feedback to adjust planning strategies. **Text2Motion** [Lin et al., 2023] goes a step further by not only generating feasible task plans (a sequence of skills) but also ensuring these plans are geometrically executable before initiation. Another direction is to utilize LLMs for translating natural language into intermediate formal task representations, **NL2TL** [Chen et al., 2024a] and **AutoTAMP** [Chen et al., 2024b] significantly enhancing task completion through auto-regressive error correction of both syntax and semantics. The planning ability of LLMs plays a great role in L2S for generating subtask chains and make plan on it to complete robotic tasks. To finish wider range of tasks, **BOSS**[Zhang et al., 2023] leverages LLM to build skill library with large amount of complex and useful skill chains generated from a set of primitive skills. Also, **SayCan** [Ahn et al., 2022] ranks all the possible skills by the task-grounding probability (usefulness) and world-grounding probability (feasibility) and select the one with highest probability at each step for LLM decision making within a given embodiment.

LLM-Based Code Generation. L2R [Yu et al., 2023] introduces a new paradigm that harnesses flexibility of reward function representations by utilizing LLMs to define reward parameters that can be optimized and accomplish variety of robotic tasks. To generate RL reward function for robotics tasks, Zeng et al. [2024] includes self-align ranking to improve the quality of generated reward function using samples ranked by both LLMs and reward function. **Text2Reward** [Xie et al., 2023] generates interpretable, free-form dense reward functions as an executable program grounded in a compact representation of the environment either by zero-shot or few-shot. **Eureka** [Ma et al., 2023] generates dense reward function without any task-specific prompting or pre-defined reward templates (zero-shot). Both **Text2Reward** and **Eureka** leverage LLM's in-context ability to improve reward function by providing human-involved feedback or automated feedback, respectively. L2S differs from T2R in its ability to generate reusable subtasks for *sequential task learning* while iteratively refining the parameterization of reward and termination functions based on subtask chain training. While Eureka's evolutionary approach can adjust reward functions, it relies heavily on costly LLM interactions for environment feedback and expensive policy training with each parameter update, and it lacks support for subtask learning. In **League++** [Li et al., 2024], the reward functions are generated by the LLM through selecting and weighting pre-defined metric functions provided by human experts. Our method differs from it in two key aspects:1)Free-form Reward Generation and 2)Reduced Human Expert Effort. Another two studies explores using LLMs for robot-centric policy generation, termed **ProgPrompt** [Singh et al., 2022] and **Code as Policies** [Liang et al., 2023], which involves generating control code directly from language instructions. L2S differs from the aforementioned works in several ways: 1) it decomposes tasks into chain of subtasks, 2) it learns subtasks as primitives and building subtask library based on the subtask chains, 3) it optimizes parameters in generated functions

to enhance task performance, and 4) it reuses subtasks and subtask chains from the library to improve learning efficiency.

B Discussion and limitations

L2S has been evaluated solely in robotic manipulation domains. Our tool demonstrates that decomposing natural language tasks into subtask chains significantly enhances performance across a broad range of robotic tasks while reducing the cost of neural policy learning. Applying LLM-based subtask discovery to other task types, such as navigation, would necessitate more advanced reasoning about environmental structures, which we leave as an avenue for future research. Additionally, L2S currently operates within state-based environments, as the LLM-generated termination functions require explicit state information to assess whether termination thresholds are met. Extending this approach to vision-based tasks may require training a supervised model that learns from state-based termination conditions, an aspect we plan to explore in future work. Lastly, LLM hallucinations present challenges in generating robust free-form reward and termination function code. Constraining code generation within a structured intermediate representation, possibly defined by a domain-specific language, might offer a balance between generation stability and the exploration of the reward space.

C Hyper-parameters

We document the hyper-parameters used for LLM code generation and RL learning algorithms in this section. For generating dense reward function code and termination condition function code, we utilized GPT-4 as the LLM agent with the sampling temperature set to 0.2 and the top_p (the cumulative probability of next token candidates) set to 0.1 for each experiment in L2S . The baseline (T2R) maintained the default values for temperature and top_p at 0.7 and 1, respectively.

For the reinforcement learning algorithm, we employed the implementation from Stable-Baselines3 (Raffin et al. [2021]) with the hyper-parameters listed in Table 2.

Table 2: Hyper-parameter of SAC algorithm applied to tasks in two benchmarks

SAC Hyper-parameters	LORL(Meta-World)	ManiSkill2
Discount factor γ	0.99	0.95
Target update frequency	2	1
Learning rate	$3e^{-4}$	$3e^{-4}$
Train frequency	1	8
Soft update τ	$5e^{-3}$	$5e^{-3}$
Gradient steps	1	4
Learning starts	4000	4000
Hidden units per layer	256	256
# of layers	3	2
Batch Size	512	1024
Initial temperature	0.1	0.2
Rollout steps per episode	500	100/200
Replaybuffer size	$5e5$	$5e5$

D Task list

In this section, we list all tasks examined in both LORL and ManiSkill2 benchmarks separately in Table. 3 and Table. 4, accompanied by their corresponding natural language instructions. Note that these instructions constitute part of the task prompt explicitly.

Table 3: List of tasks in LORL

Single-goal Task	Instruction
Push mug backward	Move the white mug backward 0.1 meter.
Push mug left	Move the white mug left 0.1 meter.
Turn faucet left	Turn the faucet handle left $\frac{\pi}{4}$ radian distance.
Turn faucet right	Turn the faucet handle right $\frac{\pi}{4}$ radian distance.
Open drawer	Open the drawer until the position of drawer box is greater than target value.

Multi-goal Task
Push mug backward and open drawer.
Open drawer and turn faucet left.
Push mug backward and turn faucet left.
Push mug backward and open drawer and turn faucet left.

Table 4: List of tasks in ManiSkill2.

Task	Instruction
Pick cube	Pick up cube A, move it to goal position and hold it.
Stack cube	Pick up cube A and place it on top of cube B.
Open cabinet drawer	A single-arm mobile robot needs to open a cabinet drawer.
Close cabinet drawer	A single-arm mobile robot needs to close a cabinet drawer.
Open drawer, Place cube and close drawer	Open the cabinet drawer, place cube it into the drawer and close the drawer.

E Additional Experiment results

In this section, we show the results of:

- The error analysis on LLM-generated functions.
- Optimizing reward and termination function parameters with various variance settings.
- Performance of L2S on long-horizon tasks.
- Performance of L2S compared with League++ [Li et al., 2024].

E.1 Error Analysis on generated functions.

For the reward generation experiment in the LORL and ManiSkill2 environments, we selected 5 simple tasks from each environment(LORL: "OpenDrawer, TurnFaucetLeft, TurnFaucetRight, PushMugBack, PushMugLeft"; ManiSkill2: "OpenDrawer, CloseDrawer, PickCube, StackCube, PlaceCubeDrawer"), as shown in Figure 5 in the paper, and queried the LLM for 20 samples per task. Across these 10 tasks, the number of subtasks generated ranged from 2 to 5. The reported results reflect the success rate for completing the entire tasks.

As shown in Table 5, L2S achieves a higher execution success rate for each generated subtask compared to the whole-task reward function generated in Text2Reward. This is because generating free-form function code for individual subtasks is inherently simpler than generating a single function for the entire task. Each subtask represents only a portion of the overall task, reducing complexity.

Table 5: Error Analysis on generated functions. We evaluated the LLM's performance in generating correct function code for both LORL and ManiSkill2 environments more than 100 samples each.

LLM(GPT-4)	LORL	ManiSkill2
Correct	92%	87%
Syntax/Shape Error	8%	13%

The results highlight the effectiveness of L2S in breaking down complex tasks into manageable components and improving the reliability of code generation.

E.2 Optimizing reward and termination function parameters with various variances.

As we provided information about the environment and additional knowledge that connects the semantics of real-world instructions to the robot environment and specifies the task's successful conditions (see Appendix E), the LLM gains some understanding of the environment's scale and selects reasonable (though not necessarily optimal) parameter mean values. By default, we set the variance of the parameters to be twice the maximum mean value generated by the LLM for the current task (a heuristic). We conducted experiments with varying alternative parameter value variances, while keeping the parameter mean value fixed. The results were obtained using three different random seeds and demonstrate that L2S consistently achieves optimal parameter values across the default setting and all tested variants.

E.2.1 LORL-Turn faucet left

For this task, we examined three different parameter variance combinations—variants 1, 2, and 3—to analyze their effects on reward and termination parameters. The first subtask in the task is trained to position the end effector around the faucet handle, with the reward function parameter defining the acceptable distance to the handle. The termination condition parameter specifies how close the end effector must be to the target position to transition to the next subtask. Results are shown in Table 6.

- **Variant 1**: The variance of the termination condition parameter is increased.
- **Variant 2**: The variance of the reward function parameter is increased.
- **Variant 3**: The variance of both parameters is increased.

Table 6: Optimizing parameters with different variances in LORL.

Reward Func Parameters / Termination Func Parameters	Initial Parameters Mean Value	Initial Parameters Variance	Optimized Params/(Std)	Success Rate/(std)	Training Cost (Timesteps)
Default	[0.01]/[0.01]	[0.2]/[0.02]	[0.107/(0.02)]/[0.013/(0.001)]	0.99/(0.01)	1e6
Variant1	[0.01]/[0.01]	[0.2]/**[0.05]**	[0.118/(0.04)]/[0.027/(0.005)]	0.89/(0.13)	1.5e6
Variant2	[0.01]/[0.01]	**[0.5]**/[0.02]	[0.16/(0.01)]/[0.015/(0.0003)]	0.97/(0.04)	1e6
Variant3	[0.01]/[0.01]	**[0.5]/[0.05]**	[0.114/(0.01)]/[0.031/(0.001)]	0.93/(0.05)	1e6

E.3 ManiSkill2-Open drawer

For this task, the parameter in the termination condition of the first subtask specifies the required proximity of the robot's end effector to the target position above the drawer handle. In the variant, we increase the variance of this parameter from the default value of 0.02 to 0.05 to evaluate its impact on performance. Results are shown in Table 7.

Table 7: Optimizing parameters with different variances in ManiSkill2.

Reward Func Parameters	Initial Parameters Mean Value	Initial Parameters Variance	Optimized Params/(Std)	Success Rate/(std)	Training Cost (Timesteps)
Default	[0.01]	[0.02]	[0.026(0.003)]	0.94/(0.06)	1e6
Variant	[0.01]	**[0.05]**	[0.031(0.006)]	0.97/(0.02)	1.5e6

E.3.1 Long-horizon tasks

We report results on complex, meaningful tasks in both the LORL and ManiSkill2 benchmarks in Table 8. Notably, we prompted GPT-4 in both L2S and Text2Reward to reuse policies learned from prior single tasks whenever possible, ensuring a fair comparison between the two approaches.

Table 8: Performance of L2S on more long-horizon tasks.

Benchmark	Task	Text2Reward(Std)	L2S(Std)
LORL	PushMugBack-OpenDrawer	0.91(0.043)	0.93(0.030)
	OpenDrawer-TurnFaucetRight	0.89(0.096)	0.93(0.062)
	MugBack-OpenDrawer-TurnFaucetRight	0.76(0.071)	0.90(0.044)
ManiSkill2	OpenDrawer-Place**TwoCubes**Drawer-CloseDrawer	0.01(0.002)	0.72(0.056)
	OpenDrawer-Place**ThreeCubes**Drawer-CloseDrawer	0.01(0.001)	0.54(0.032)

E.4 Performance of L2S compared with League++

Table 9: Descriptions of various metrics functions.

Metrics Function	**Definition**
dis_to_obj	Distance between the gripper and the object
perpendicular_dis	Distance between object and gripper along the normal line
in_grasp	If the object is grasped by the gripper
drawer_opened (LORL)	The drawer is opened enough or not.
faucet_turned (LORL)	The faucet handle is turned away enough or not.
mug_pushed (LORL)	The mug is pushed away enough or not.
cube_placed (ManiSkill2)	The cube is placed in the drawer or not.

Due to the lack of open-sourced code, we were unable to implement the feedback loop described in League++. Instead, we manually selected high-quality LLM-generated subtask samples for RL training, which might not fully replicate the intended process in League++. During the implementation, we limited the LLM to selecting from a set of Metric Functions similar to those explicitly listed in the League++ paper. Table 9 shows the Metric Functions we designed for this comparison. Our evaluation includes the 1) "Open Drawer," 2) "Turn Faucet Left," and 3) "Push Mug Back" tasks from the LORL benchmark, as well as the "Place Cube Drawer" task from the ManiSkill2 benchmark. Subtask policies are learned using League++ generated reward functions, together with parameter optimizing method from L2S. All results were obtained using three different random seeds to ensure reliability. League++ underperforms compared to L2S in our implementation, as shown in Table 10.

Table 10: Comparison of success rates for different tasks between League++ and L2S.

Tasks	**League++ Success Rate (Std)**	**L2S Success Rate (Std)**
LORL-Open Drawer	0.83 (0.06)	0.95 (0.02)
LORL-Turn Faucet Left	0.58 (0.15)	0.99 (0.01)
LORL-Push Mug Back	0.13 (0.13)	0.96 (0.04)
ManiSkill2-Place Cube Drawer	0.78 (0.07)	0.92 (0.07)

League++'s reliance on predefined Metric Functions may limit its ability to capture the full complexity of tasks or appropriately penalize suboptimal behavior, potentially reducing overall performance. This result reinforces the advantage of using free-form reward functions to improve the effectiveness and adaptability of subtask training.

F Subtask reuse and refinement on complex task

In this section, we show the result of reusing subtasks or subtask chain from basic single-goal task to complete complex tasks in Fig. 8. We showcases the effectiveness of subtasks refinement in L2S when necessary. For example, the Task4 "Turn faucet left and open drawer" performs only 12% success ratio with directly reusing subtasks from subtask library. However, with refinement by L2S , the performance can be greatly improved to close to perfect, with evaluation curve shown in Fig. 9.

Task	Task Description
Task1	Push mug backward and open drawer
Task2	Open drawer and turn faucet left
Task3	Open drawer and push white mug backward
Task4	Turn faucet left and open drawer
Task5	Push mug backward and turn faucet left
Task6	Push mug backward and open drawer and turn faucet left

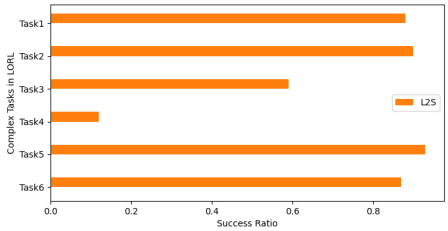

Figure 8: Complex task instruction(left) and success ratio on complex tasks in LORL environment(right).

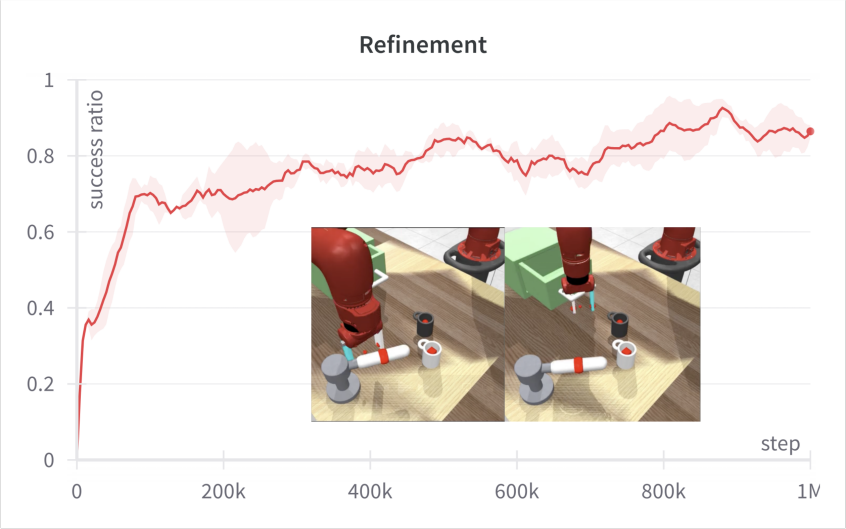

Figure 9: Success ratio on refining reused subtask in task "Turn faucet left and open drawer".

G LLM prompt

A prompt used in L2S consists of following components: *introduction*, *environment description*, *additional environmental knowledge*, *tips and tricks*, *instruction hint*, and *learned subtask library*. Here we use an example of the prompt for ManiSKill2 manipulation tasks to demonstrate how each component is formatted:

Listing 1 Introduction.

```
introduction = """
You are an expert in robotics, reinforcement learning, task decomposing, task planning and code
generation. We are going to control a robotic arm to complete some given tasks. The robotic arm is a
7-DoF Fetch Mobile Manipulator with a two-fingered parallel gripper. The robotic arm is controlled by
small displacements of the gripper in Cartesian coordinates and the inverse kinematics are computed
internally by the MuJoCo framework. The gripper can be opened or closed in order to perform the
grasping operation of pick and place.

The action space of the robot is Box(np.array([-1, -1, -1, -np.pi, -1]), np.array([1, 1, 1, np.pi, 1]),).

| Num  | Action                                                              |  Unit         |
| ---- | ------------------------------------------------------------------- |  ------------ |
| 0    | Displacement of the end effector in the x direction dx              |  position (m) |
| 1    | Displacement of the end effector in the y direction dy              |  position (m) |
| 2    | Displacement of the end effector in the z direction dz              |  position (m) |
| 3    | Angular displacement of the end effector                            |  position (m) |
| 4    | Positional displacement per timestep of each finger of the gripper|  position (m) |

Now I want you to help me
1) decompose the robotic task into sequences of subtasks
2) write dense reward functions and termination conditions of reinforcement learning for each subtask.
3) make plan on the subtasks to finish the robotic task.

I'll give you the attributes of the environment and robotic arm itself. You can use these class attributes
to write the reward function.
"""
```

Listing 2 Environment description.

```
environment_description = """
The following classes provide the information about the robotic arm and all objects in the environment.

class BaseEnv(gym.Env):
    self.robot : SawyerRobot # the robot in the environment
    self.white_mug : MugObject # the white mug in the environment
    self.black_mug : MugObject # the black mug in the environment

    self.drawer_box_position : numpy.float64 # indicate the 1D relative position of the drawer box.
                                             # The position range is between [-0.16, 0] meter.
    self.init_box_handle : np.ndarray[(3,)] # indicate the initial 3D position of the handle of drawer box
    self.init_drawer_box_position : numpy.float64 # indicate the initial 1D relative position of
                                                  # the drawer box
"""
```

Listing 3 Additional environment knowledge.

```
env_additional_knowledge = """
Additional knowledge:
1. For the robotic arm gripper and all the objects in the environment, the direction words in the
following task are defined as:
    1) "Left" or "right" means towards the positive or negative x-axis with respect to the related object
    position, respectively. X-axis is corresponding to the first value in the 3D position with form
    "np.ndarray[(3,)]". For example, x-axis of mug is "mug.position[0]".
    2) "Forward/Front" or "backward/Back" means towards the positive or negative y-axis with respect to
    the reference object position, respectively. Y-axis is corresponding to the second value in the
    3D position with form "np.ndarray[(3,)]". For example, y-axis of a mug is "mug.postion[1]".
    3) "Above" or "below" means towards the positive or negative z-axis with respect to the reference
    position, respectively. Z-axis is corresponding to the third value in the 3D position with
    form "np.ndarray[(3,)]".
    For example, z-axis of mug is "mug.position[2]".
    4) Specially, for the object faucet, "turn left" or "turn right" means turning faucet that increases
    or decreases the faucet handle angular position.
2. In order to compare the replative positions of different items in the environment, including
the robotic arm gripper and all the objects, you must first identify the attributes that represents
the 3D-positions, and then use these attributes for computation. In practice, the relative position
words in the following task are defined as:
    1) "One item is on the left or on the right of the other item" means the item is on the positive or
    negative x-axis direction with respect to the other item, respectively. X-axis is corresponding
    to the first value in the 3D position with form "np.ndarray[(3,)]".
    2) "One item is in front of or at the back of the other item" means the item is on the positive or
    negative y-axis direction with respect to the other item, respectively. Y-axis is corresponding
    to the second value in the 3D position with form "np.ndarray[(3,)]".
    3) "One item is above or below the other item" means the item is on the positive or negative z-axis
    direction with respect to the other item, respectively. Z-axis is corresponding to the third value
    in the 3D position with form "np.ndarray[(3,)]".
3. Tasks about moving mug are considered successful when mug is moved at least 0.1 meter towards the
correct direction compared with the object's initial position.
4. Tasks about turning faucet are considered successful when faucet is turned at least np.pi/4 radian
towards the correct direction compared with the object initial position.
5. Tasks about opening or closing drawer are considered successful when drawer box is fully open or
fully closes. Drawer fully open means drawer box position is smaller than -0.15 meter.
Drawer fully closed means drawer box position is greater than -0.01 meter.
"""
```

Listing 4 Instruction hint.

```
instruction_hint = """
Task to be fulfilled: {instruction}.
Here is the instruction:
Please think step by step and finish the following requirements one by one in order:
    1. Tell me what does this task mean. If it is a complex task, identify how many simple task you can
    identify.
    2. Decompose a whole task into a set of possible subtasks and plan on the subtasks to finish each simple
    task. You can refer to the above examples if provided after the intruction part.
    3. Identify which example you are referring to, if any.
    4. Identify the index of subtask that terminate each simple task as you have answered above. Save the
    index of subtask in "simple_task_termination_subtask = [...]"
    5. For each subtask, design a pair of dense reward function and terminition condition function based
    on the purpose of the subtask. Write down the pair of functions one by one with the following format:
        1) Make each pair of reward function and termination function a separate python code piece
        "```python ```".
        2) Dense reward function is used in reinforcement learning, here are the requirements:
            a. Create a list "params = [...]" containing extra parameters that never exist for computing
            reward (if any). But you should not include any threshold value, reward term weight
            or attributes that already exist in the above environment information in the list "params",
            e.g, termination threshold value, reward term weight, the position information of any item.
            Make sure every parameter in list "params = [...]" is used in the dense reward function.
            b. Define the reward term one by one and explain the purpose of each reward term as comment.
            c. This function starts with `def compute_dense_reward_subtask_NUM(self, action, obs) -> float`.
            It only returns variable `reward : float`.  Replace 'NUM' with the number of subtask.
        3) Terminition condition function decides whether the subtask is successful, here are the
        requirements:
            a. Copy list "params = [...]" from dense reward function and paste it into the terminition
            condition function. Any value in list "params" shuold not be used as termination threshold.
            b. Create a list "t_params = [...]" containing the value used as termination threshold if the
            corresponding subtask is not in "simple_task_termination_subtask". Make sure every parameter
            in list "t_params = [...]" is used later in terminition condition function.
            c. Make lists "params = [...]" and "t_params = [...]" don't conflict with each other because
            they are used for different purposes.
            d. This function starts with  `def termination_subtask_NUM(self, obs) -> bool`. It only returns
            variable `done : bool`. Value of `done : bool` should be decided before it is returned.
            Replace 'NUM' with the number of subtask.
"""
```

Listing 5 Few-shot example.

```
Instances of Few-shot Examples:
1.Task to be fulfilled: Turn an object with a handle left.
Corresponding subtasks and sequence of subtasks for accomplishing the task:
  Subtask 1: Align the robot arm end-effector to a 3D position on the right of the object handle with
  some offset.
  Subtask 2: Move robot arm end-effector and turn the object handle left.
  The sequence for accomplishing the task could be: Subtask 1 -> Subtask 2.
2.Task to be fulfilled: In the MuJoCo PickAndPlace environment, pick up a box and move it to the 3D
goal position and hold it there.
Corresponding subtasks and sequence of subtasks for accomplishing the task :
  Subtask 1. Navigate gripper to the box.
  Subtask 2. Grasp the box and move the box to the goal position and hold it.
  The sequence for accomplishing the task could be: Subtask 1 -> Subtask 2.
```

Subtasks library prompt. A complete L2S prompt is the ordered concatenation of the above components. Additionally, we could also ask the LLM to generate response considering reusing given library of subtasks (in listing 6). Such a prompt makes it possible for L2S to reuse either subtasks generated by language model or reference subtasks given by human experts in the code generation process, thus potentially facilitate the subtask discovery and training.

Listing 6 Subtasks library prompt.

```
subtasks_lib_prompt = """
After finishing the job above, I have one more job for you.
Now we have a subtasks library which store the already trained subtasks in a list format, each element in the
list mapping  the stored subtasks number and the discription of the subtasks.
subtasks_library=[
    "1":"Navigate to the position on the left side of the faucet handle and keep some distance away
    from it. This subtask has paramters as safe distance between gripper and faucet handle that can
    be tuned.",
    "2":"Navigate gripper to the intermediate position on the forward direction of the white mug
    and maintain a safe distance from the white mug.",
    "3":"Move gripper and push the faucet to the right. This subtask can not be modified.",
    ]

What you should do is:
    1) First, think the meaning of each subtasks. You should clarify the following attributes of each subtask:
    the objects involved in the subtask, the relation between objects and the goal that the subtask finally
    should achieve.
    2) Then, with the decomposed subtask of current task and your understanding of the subtasks in subtask
    library, please think about which subtask in the library do the exact same work as some subtask(s) in
    current task and can be reused.
    3) Lastly, Please give back the pair-wise mapping from current subtask number to the subtask number in
    skills library with python JSON format. Each pair of subtask models selected must have the same
    attribute. That's means even if two subtasks are very similar but not the same, you should not select
    them because it need extra training. And you should explain the reason why you make such pairing.
"""
```

H Examples of reward functions and termination condition functions

In this section, we provides example pairs of generated reward functions and termination functions generated by LLM to solve given tasks. Each figure includes one dense reward function and its corresponding termination function to constitute a complete subtask. Numbers in the suffix of the function names denote the indices of the subtasks.

Turn faucet left. Fig. 10 and 11 show the generated subtasks. In this task, the language model proposes a simple yet effective two-stage solution. Specifically, the first subtask is responsible for aligning the robot arm end-effector to a 3D position on the right of the faucet handle. Then the second subtask moves robot arm end-effector and turn the faucet handle left and finally solve the task.

```
def compute_dense_reward_0(self, action, obs, params) -> float:
    params = [0.01]
    # Reward term 1: The negative distance between robot's end-effector and the target
    # position on the right of the faucet handle.
    target_position = obs['current_state'][10:13] + np.array([params[0], 0, 0])
    distance = np.linalg.norm(obs['current_state'][:3] - target_position)
    reward = -distance

    # Reward term 2: Regularization term on the action, to encourage smaller actions
    # for smoother movements.
    action_reg = 0.1 * np.linalg.norm(action)
    reward -= action_reg

    return reward

def termination_0(self, obs, params, t_params) -> bool:
    params = [0.01]
    t_params = [0.01]
    # The subtask is successful if the robot's end-effector is close
    # enough to the target position
    target_position = obs['current_state'][10:13] + np.array([params[0], 0, 0])
    distance = np.linalg.norm(obs['current_state'][:3] - target_position)
    done = distance < t_params[0]
    return done
```

Figure 10: Subtask 0 for turn faucet left.

```
def compute_dense_reward_1(self, action, obs, params) -> float:
    params = []
    # Reward term 1: The negative difference between current and initial angular
    # position of faucet handle.
    angular_difference = obs['current_state'][13] - obs['initial_state'][13]
    reward = -angular_difference

    # Reward term 2: Regularization term on the action, to encourage smaller
    # actions for smoother movements.
    action_reg = 0.1 * np.linalg.norm(action)
    reward -= action_reg

    return reward

def termination_1(self, obs, params, t_params) -> bool:
    t_params = [0.78]
    # The skill is successful if the faucet handle has been turned more than 0.78 radian
    # to the left
    angular_difference = obs['current_state'][13] - obs['initial_state'][13]
    done = angular_difference < -t_params[0]
    return done
```

Figure 11: Subtask 1 for turn faucet left.

Open drawer. Fig. 12, 13 and 14 demonstrate the three subtass in the open drawer task decomposition. Concretely speaking, the response from LLM is:

Subtask 1: Move the robot arm end-effector to a 3D position above the drawer box handle.

Subtask 2: Align robot arm end-effector with the drawer box handle.

Subtask 3: Move robot arm end-effector to open the drawer.

The sequence for accomplishing the task could be: Subtask 1 -> Subtask 2 -> Subtask 3.

```
def compute_dense_reward_0(self, action, obs, params) -> float:
    params = [0.01]
    # Reward term 1: The negative distance between the robot's end-effector and the
    # target position above the drawer box handle.
    reward_term_1 = -np.linalg.norm(obs['current_state'][:3] - \
        (obs['current_state'][14:17] + np.array([0, 0, params[0]])))
    # Reward term 2: Regularization term on the robot's action.
    reward_term_2 = -np.linalg.norm(action)
    # The total reward is the weighted sum of the reward terms.
    reward = 1 * reward_term_1 + 0.1 * reward_term_2
    return reward

def termination_0(self, obs, params, t_params) -> bool:
    params = [0.01]
    t_params = [0.01]
    # The subtask is considered successful if the distance between the robot's
    # end-effector and the target position is less than a threshold.
    done = np.linalg.norm(obs['current_state'][:3] - \
        (obs['current_state'][14:17] + np.array([0, 0, params[0]]))
    ) < t_params[0]
    return done
```

Figure 12: Subtask 0 for open drawer.

```
def compute_dense_reward_1(self, action, obs, params) -> float:
    params = []
    # Reward term 1: The negative distance between the robot's end-effector and the
    # drawer box handle.
    reward_term_1 = -np.linalg.norm(obs['current_state'][:3] - \
        obs['current_state'][14:17])
    # Reward term 2: Regularization term on the robot's action.
    reward_term_2 = -np.linalg.norm(action)
    # The total reward is the weighted sum of the reward terms.
    reward = 1 * reward_term_1 + 0.1 * reward_term_2
    return reward

def termination_1(self, obs, params, t_params) -> bool:
    t_params = [0.01]

Stack cube. The stack cube task in the ManiSkill2 is one of the most complicated task in our experiments. To solve this task, the LLM provides a chain of subtasks from subtask 0 all the way to subtask 4 (see Fig. 15, 16, 17, 18 and 19). The corresponding response from LLM is:

The subtasks and sequence of subtasks for accomplishing each simple task are:

- Subtask 1: Navigate gripper to cube A.

- *Subtask 2: Grasp cube A.*

- *Subtask 3: Lift cube A in the air.*

- *Subtask 4: Move cube A to the position above cube B.*

- *Subtask 5: Release cube A.*

The sequence for accomplishing the task could be: Subtask 1 -> Subtask 2 -> Subtask 3 -> Subtask 4 -> Subtask 5.

```
def compute_dense_reward_0(self, action, obs, params) -> float:
    import numpy as np
    # Reward term 1: the distance between robot's gripper and cube A
    dist_to_cubeA = np.linalg.norm(self.tcp.pose.p - self.cubeA.pose.p)
    # Reward term 2: regularization of the robot's action
    action_reg = np.linalg.norm(action)
    reward = -dist_to_cubeA - 0.1 * action_reg
    return reward

def termination_0(self, obs, params, t_params) -> bool:
    t_params = [0.01]
    dist_to_cubeA = np.linalg.norm(self.tcp.pose.p - self.cubeA.pose.p)
    done = dist_to_cubeA < t_params[0]
    return done
```

NeurIPS Paper Checklist

1. **Claims**

   Question: Do the main claims made in the abstract and introduction accurately reflect the paper's contributions and scope?

   Answer: [Yes]

   Justification: In section 1

   Guidelines:

   - The answer NA means that the abstract and introduction do not include the claims made in the paper.
   - The abstract and/or introduction should clearly state the claims made, including the contributions made in the paper and important assumptions and limitations. A No or NA answer to this question will not be perceived well by the reviewers.
   - The claims made should match theoretical and experimental results, and reflect how much the results can be expected to generalize to other settings.
   - It is fine to include aspirational goals as motivation as long as it is clear that these goals are not attained by the paper.

2. **Limitations**

   Question: Does the paper discuss the limitations of the work performed by the authors?

   Answer: [Yes]

   Justification: In appendix B

   Guidelines:

   - The answer NA means that the paper has no limitation while the answer No means that the paper has limitations, but those are not discussed in the paper.
   - The authors are encouraged to create a separate "Limitations" section in their paper.
   - The paper should point out any strong assumptions and how robust the results are to violations of these assumptions (e.g., independence assumptions, noiseless settings, model well-specification, asymptotic approximations only holding locally). The authors should reflect on how these assumptions might be violated in practice and what the implications would be.
   - The authors should reflect on the scope of the claims made, e.g., if the approach was only tested on a few datasets or with a few runs. In general, empirical results often depend on implicit assumptions, which should be articulated.
   - The authors should reflect on the factors that influence the performance of the approach. For example, a facial recognition algorithm may perform poorly when image resolution is low or images are taken in low lighting. Or a speech-to-text system might not be used reliably to provide closed captions for online lectures because it fails to handle technical jargon.
   - The authors should discuss the computational efficiency of the proposed algorithms and how they scale with dataset size.
   - If applicable, the authors should discuss possible limitations of their approach to address problems of privacy and fairness.
   - While the authors might fear that complete honesty about limitations might be used by reviewers as grounds for rejection, a worse outcome might be that reviewers discover limitations that aren't acknowledged in the paper. The authors should use their best judgment and recognize that individual actions in favor of transparency play an important role in developing norms that preserve the integrity of the community. Reviewers will be specifically instructed to not penalize honesty concerning limitations.

3. **Theory assumptions and proofs**

   Question: For each theoretical result, does the paper provide the full set of assumptions and a complete (and correct) proof?

   Answer: [Yes]

Justification: In section 3

Guidelines:

- The answer NA means that the paper does not include theoretical results.
- All the theorems, formulas, and proofs in the paper should be numbered and cross-referenced.
- All assumptions should be clearly stated or referenced in the statement of any theorems.
- The proofs can either appear in the main paper or the supplemental material, but if they appear in the supplemental material, the authors are encouraged to provide a short proof sketch to provide intuition.
- Inversely, any informal proof provided in the core of the paper should be complemented by formal proofs provided in appendix or supplemental material.
- Theorems and Lemmas that the proof relies upon should be properly referenced.

4. **Experimental result reproducibility**

   Question: Does the paper fully disclose all the information needed to reproduce the main experimental results of the paper to the extent that it affects the main claims and/or conclusions of the paper (regardless of whether the code and data are provided or not)?

   Answer: [Yes]

   Justification: In section 4

   Guidelines:

   - The answer NA means that the paper does not include experiments.
   - If the paper includes experiments, a No answer to this question will not be perceived well by the reviewers: Making the paper reproducible is important, regardless of whether the code and data are provided or not.
   - If the contribution is a dataset and/or model, the authors should describe the steps taken to make their results reproducible or verifiable.
   - Depending on the contribution, reproducibility can be accomplished in various ways. For example, if the contribution is a novel architecture, describing the architecture fully might suffice, or if the contribution is a specific model and empirical evaluation, it may be necessary to either make it possible for others to replicate the model with the same dataset, or provide access to the model. In general. releasing code and data is often one good way to accomplish this, but reproducibility can also be provided via detailed instructions for how to replicate the results, access to a hosted model (e.g., in the case of a large language model), releasing of a model checkpoint, or other means that are appropriate to the research performed.
   - While NeurIPS does not require releasing code, the conference does require all submissions to provide some reasonable avenue for reproducibility, which may depend on the nature of the contribution. For example
     (a) If the contribution is primarily a new algorithm, the paper should make it clear how to reproduce that algorithm.
     (b) If the contribution is primarily a new model architecture, the paper should describe the architecture clearly and fully.
     (c) If the contribution is a new model (e.g., a large language model), then there should either be a way to access this model for reproducing the results or a way to reproduce the model (e.g., with an open-source dataset or instructions for how to construct the dataset).
     (d) We recognize that reproducibility may be tricky in some cases, in which case authors are welcome to describe the particular way they provide for reproducibility. In the case of closed-source models, it may be that access to the model is limited in some way (e.g., to registered users), but it should be possible for other researchers to have some path to reproducing or verifying the results.

5. **Open access to data and code**

   Question: Does the paper provide open access to the data and code, with sufficient instructions to faithfully reproduce the main experimental results, as described in supplemental material?

Answer: [No]

Justification: We would provide an anonymous code repo later.

Guidelines:

- The answer NA means that paper does not include experiments requiring code.
- Please see the NeurIPS code and data submission guidelines (https://nips.cc/public/guides/CodeSubmissionPolicy) for more details.
- While we encourage the release of code and data, we understand that this might not be possible, so "No" is an acceptable answer. Papers cannot be rejected simply for not including code, unless this is central to the contribution (e.g., for a new open-source benchmark).
- The instructions should contain the exact command and environment needed to run to reproduce the results. See the NeurIPS code and data submission guidelines (https://nips.cc/public/guides/CodeSubmissionPolicy) for more details.
- The authors should provide instructions on data access and preparation, including how to access the raw data, preprocessed data, intermediate data, and generated data, etc.
- The authors should provide scripts to reproduce all experimental results for the new proposed method and baselines. If only a subset of experiments are reproducible, they should state which ones are omitted from the script and why.
- At submission time, to preserve anonymity, the authors should release anonymized versions (if applicable).
- Providing as much information as possible in supplemental material (appended to the paper) is recommended, but including URLs to data and code is permitted.

6. **Experimental setting/details**

   Question: Does the paper specify all the training and test details (e.g., data splits, hyperparameters, how they were chosen, type of optimizer, etc.) necessary to understand the results?

   Answer: [Yes]

   Justification: In both Experiment and Result sections

   Guidelines:

   - The answer NA means that the paper does not include experiments.
   - The experimental setting should be presented in the core of the paper to a level of detail that is necessary to appreciate the results and make sense of them.
   - The full details can be provided either with the code, in appendix, or as supplemental material.

7. **Experiment statistical significance**

   Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments?

   Answer: [Yes]

   Justification: Please see figures in the Result section.

   Guidelines:

   - The answer NA means that the paper does not include experiments.
   - The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper.
   - The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions).
   - The method for calculating the error bars should be explained (closed form formula, call to a library function, bootstrap, etc.)
   - The assumptions made should be given (e.g., Normally distributed errors).
   - It should be clear whether the error bar is the standard deviation or the standard error of the mean.

- It is OK to report 1-sigma error bars, but one should state it. The authors should preferably report a 2-sigma error bar than state that they have a 96% CI, if the hypothesis of Normality of errors is not verified.
- For asymmetric distributions, the authors should be careful not to show in tables or figures symmetric error bars that would yield results that are out of range (e.g. negative error rates).
- If error bars are reported in tables or plots, The authors should explain in the text how they were calculated and reference the corresponding figures or tables in the text.

8. **Experiments compute resources**

   Question: For each experiment, does the paper provide sufficient information on the computer resources (type of compute workers, memory, time of execution) needed to reproduce the experiments?

   Answer: [Yes]

   Justification: We provide the type of GPU we conducted experiments on.

   Guidelines:

   - The answer NA means that the paper does not include experiments.
   - The paper should indicate the type of compute workers CPU or GPU, internal cluster, or cloud provider, including relevant memory and storage.
   - The paper should provide the amount of compute required for each of the individual experimental runs as well as estimate the total compute.
   - The paper should disclose whether the full research project required more compute than the experiments reported in the paper (e.g., preliminary or failed experiments that didn't make it into the paper).

9. **Code of ethics**

   Question: Does the research conducted in the paper conform, in every respect, with the NeurIPS Code of Ethics https://neurips.cc/public/EthicsGuidelines?

   Answer: [Yes]

   Justification: Of course.

   Guidelines:

   - The answer NA means that the authors have not reviewed the NeurIPS Code of Ethics.
   - If the authors answer No, they should explain the special circumstances that require a deviation from the Code of Ethics.
   - The authors should make sure to preserve anonymity (e.g., if there is a special consideration due to laws or regulations in their jurisdiction).

10. **Broader impacts**

    Question: Does the paper discuss both potential positive societal impacts and negative societal impacts of the work performed?

    Answer: [No]

    Justification: We think it is not so related to discuss it.

    Guidelines:

    - The answer NA means that there is no societal impact of the work performed.
    - If the authors answer NA or No, they should explain why their work has no societal impact or why the paper does not address societal impact.
    - Examples of negative societal impacts include potential malicious or unintended uses (e.g., disinformation, generating fake profiles, surveillance), fairness considerations (e.g., deployment of technologies that could make decisions that unfairly impact specific groups), privacy considerations, and security considerations.
    - The conference expects that many papers will be foundational research and not tied to particular applications, let alone deployments. However, if there is a direct path to any negative applications, the authors should point it out. For example, it is legitimate to point out that an improvement in the quality of generative models could be used to

generate deepfakes for disinformation. On the other hand, it is not needed to point out that a generic algorithm for optimizing neural networks could enable people to train models that generate Deepfakes faster.

- The authors should consider possible harms that could arise when the technology is being used as intended and functioning correctly, harms that could arise when the technology is being used as intended but gives incorrect results, and harms following from (intentional or unintentional) misuse of the technology.
- If there are negative societal impacts, the authors could also discuss possible mitigation strategies (e.g., gated release of models, providing defenses in addition to attacks, mechanisms for monitoring misuse, mechanisms to monitor how a system learns from feedback over time, improving the efficiency and accessibility of ML).

11. **Safeguards**

    Question: Does the paper describe safeguards that have been put in place for responsible release of data or models that have a high risk for misuse (e.g., pretrained language models, image generators, or scraped datasets)?

    Answer: [No]

    Justification: No risk.

    Guidelines:

    - The answer NA means that the paper poses no such risks.
    - Released models that have a high risk for misuse or dual-use should be released with necessary safeguards to allow for controlled use of the model, for example by requiring that users adhere to usage guidelines or restrictions to access the model or implementing safety filters.
    - Datasets that have been scraped from the Internet could pose safety risks. The authors should describe how they avoided releasing unsafe images.
    - We recognize that providing effective safeguards is challenging, and many papers do not require this, but we encourage authors to take this into account and make a best faith effort.

12. **Licenses for existing assets**

    Question: Are the creators or original owners of assets (e.g., code, data, models), used in the paper, properly credited and are the license and terms of use explicitly mentioned and properly respected?

    Answer: [Yes]

    Justification: We choose CC-BY 4.0

    Guidelines:

    - The answer NA means that the paper does not use existing assets.
    - The authors should cite the original paper that produced the code package or dataset.
    - The authors should state which version of the asset is used and, if possible, include a URL.
    - The name of the license (e.g., CC-BY 4.0) should be included for each asset.
    - For scraped data from a particular source (e.g., website), the copyright and terms of service of that source should be provided.
    - If assets are released, the license, copyright information, and terms of use in the package should be provided. For popular datasets, `paperswithcode.com/datasets` has curated licenses for some datasets. Their licensing guide can help determine the license of a dataset.
    - For existing datasets that are re-packaged, both the original license and the license of the derived asset (if it has changed) should be provided.
    - If this information is not available online, the authors are encouraged to reach out to the asset's creators.

13. **New assets**

    Question: Are new assets introduced in the paper well documented and is the documentation provided alongside the assets?

Answer: [Yes]

Justification: Some modification on the environment setting in benchmarks has been well commented.

Guidelines:

- The answer NA means that the paper does not release new assets.
- Researchers should communicate the details of the dataset/code/model as part of their submissions via structured templates. This includes details about training, license, limitations, etc.
- The paper should discuss whether and how consent was obtained from people whose asset is used.
- At submission time, remember to anonymize your assets (if applicable). You can either create an anonymized URL or include an anonymized zip file.

14. **Crowdsourcing and research with human subjects**

Question: For crowdsourcing experiments and research with human subjects, does the paper include the full text of instructions given to participants and screenshots, if applicable, as well as details about compensation (if any)?

Answer: [No]

Justification: No crowdsourcing experiments or research with human subjects.

Guidelines:

- The answer NA means that the paper does not involve crowdsourcing nor research with human subjects.
- Including this information in the supplemental material is fine, but if the main contribution of the paper involves human subjects, then as much detail as possible should be included in the main paper.
- According to the NeurIPS Code of Ethics, workers involved in data collection, curation, or other labor should be paid at least the minimum wage in the country of the data collector.

15. **Institutional review board (IRB) approvals or equivalent for research with human subjects**

Question: Does the paper describe potential risks incurred by study participants, whether such risks were disclosed to the subjects, and whether Institutional Review Board (IRB) approvals (or an equivalent approval/review based on the requirements of your country or institution) were obtained?

Answer: [No]

Justification: No participant involved.

Guidelines:

- The answer NA means that the paper does not involve crowdsourcing nor research with human subjects.
- Depending on the country in which research is conducted, IRB approval (or equivalent) may be required for any human subjects research. If you obtained IRB approval, you should clearly state this in the paper.
- We recognize that the procedures for this may vary significantly between institutions and locations, and we expect authors to adhere to the NeurIPS Code of Ethics and the guidelines for their institution.
- For initial submissions, do not include any information that would break anonymity (if applicable), such as the institution conducting the review.

16. **Declaration of LLM usage**

Question: Does the paper describe the usage of LLMs if it is an important, original, or non-standard component of the core methods in this research? Note that if the LLM is used only for writing, editing, or formatting purposes and does not impact the core methodology, scientific rigorousness, or originality of the research, declaration is not required.

Answer: [Yes]

Justification: Using LLM for reinforcement learning is well discussed in this paper.

Guidelines:

- The answer NA means that the core method development in this research does not involve LLMs as any important, original, or non-standard components.
- Please refer to our LLM policy (https://neurips.cc/Conferences/2025/LLM) for what should or should not be described.
